Prelim. Study	<b>common</b> / uncommon	-0.35	9.50E-67	0.30	2.78E-48
	<b>emotional</b> / unemotional	0.01	6.11E-01	0.16	4.09E-14
	<b>friendly</b> / unfriendly	-0.13	1.40E-09	0.26	1.18E-34

*Notes.* A chart of the  $r$  and  $p$  values from Pearson's correlations between each attribute and HR and FAR. HR and FAR are logit-transformed and attribute scores are z-score transformed. Green cells indicate positive correlations (corresponding to positive-valence attributes), while red cells indicate negative correlations (corresponding to negative-valence attributes). Darkness of color is determined by effect size, as determined by Cohen's effect size for  $r$ .

Notes. Similar to Table 2-3 in the main text, this table shows the  $\beta$  weight,  $t$  statistic, and  $p$ -value for multiple linear regression models with the twenty attributes (Oosterhof & Todorov, 2008; Vokey & Read, 1992) as well as a randomly split-half HR regressor, with the model predicting the other split-half of HR. The model was run 25 times, with different random HR split-halves each time. This table shows the statistics for the worst-performing (minimum fit) and best-performing (maximum fit) models of the 25. Attributes are z-score transformed, and HR scores are logit-transformed. Colored cells indicate cells with significant values, with darker cells significant at  $p < 0.01$ , lighter cells at  $p < 0.05$ , and white cells are non-significant. Green cells indicate positive values (aligning with the positive attribute) and red cells indicate negative values (aligning with the negative attribute).
